

# Chapter 1

## Regular Languages

### 1.1 Deterministic Finite State Automata

**Definition 1.1.1.** An **alphabet**  $\Sigma$  is a finite set of symbols.

- A **string** over  $\Sigma$  is a finite sequence of symbols from  $\Sigma$ .
- The **length** of a string  $w$ , denoted by  $|w|$ , is the number of symbols it contains.
- The string of length 0 is called the **empty string**, denoted by  $\epsilon$ .

**Definition 1.1.2.** Let  $\Sigma$  be an alphabet.

- For any nonnegative integer  $n$ ,  $\Sigma^n$  denotes the set of words of length  $n$ .
- $\Sigma^*$  denotes the set of all strings over  $\Sigma$ .
- A **language** over  $\Sigma$  is a subset of  $\Sigma^*$ .

**Definition 1.1.3.** A **deterministic finite state automaton** (DFA) is a system  $\mathcal{A} = (\Sigma, Q, q_0, F, \delta)$ , where each component is as follows.

- $\Sigma$  is the alphabet.
- $Q$  is a finite set of **states**.
- $q_0 \in Q$  is the **initial** state.
- $F \subseteq Q$  is the set of **accepting** states.
- $\delta$  is the **transition function** from  $Q \times \Sigma$  to  $Q$ .

**Definition 1.1.4.** The **run** of DFA  $\mathcal{A} = (\Sigma, Q, q_0, F, \delta)$  on an input string  $w = a_1 \cdots a_n$  over  $\Sigma$  is the sequence of states

$$r = (r_0, r_1, \dots, r_n)$$

where  $r_0 = q_0$  and  $\delta(r_{i-1}, a_i) = r_i$  for each  $i \in \{1, \dots, n\}$ .

- $r$  is an **accepting** run if  $r_n \in F$ .
- We say that  $\mathcal{A}$  **accepts**  $w$  if the run of  $\mathcal{A}$  on  $w$  is an accepting run.

- The language of all strings accepted by  $\mathcal{A}$  is denoted by  $L(\mathcal{A})$ .
- A language  $L$  is **regular** if there is a DFA  $\mathcal{A}$  with  $L = L(\mathcal{A})$ .

**Remark.**

- For DFA  $\mathcal{A} = (\Sigma, Q, q_0, F, \delta)$ , the empty string  $\epsilon$  is accepted by  $\mathcal{A}$  if and only if  $q_0 \in F$ .

## 1.2 Nondeterministic Finite State Automata

**Definition 1.2.1.** A **nondeterministic finite state automaton** (NFA) is a system  $\mathcal{A} = (\Sigma, Q, q_0, F, \delta)$ , where each component is as follows.

- $\Sigma$  is the alphabet.
- $Q$  is a finite set of **states**.
- $q_0 \in Q$  is the **initial** state.
- $F \subseteq Q$  is the set of **accepting** states.
- $\delta \subseteq Q \times \Sigma \times Q$  is the **transition relation**.

**Definition 1.2.2.** A **run** of NFA  $\mathcal{A} = (\Sigma, Q, q_0, F, \delta)$  on an input string  $w = a_1 \cdots a_n$  over  $\Sigma$  is the sequence of states

$$r = (r_0, r_1, \dots, r_n)$$

where  $r_0 = q_0$  and  $(r_{i-1}, a_i, r_i) \in \delta$  for each  $i \in \{1, \dots, n\}$ .

- $r$  is an **accepting** run if  $r_n \in F$ .
- We say that  $\mathcal{A}$  **accepts**  $w$  if there is an accepting run of  $\mathcal{A}$  on  $w$ .
- The language of all strings accepted by  $\mathcal{A}$  is denoted by  $L(\mathcal{A})$ .

**Theorem 1.2.3.** For every NFA  $\mathcal{A}$ , there is a DFA  $\hat{\mathcal{A}}$  with  $L(\mathcal{A}) = L(\hat{\mathcal{A}})$ .

*Proof.* Let  $\mathcal{A} = (\Sigma, Q, q_0, F, \delta)$ . We construct  $\hat{\mathcal{A}} = (\Sigma, \hat{Q}, \hat{q}_0, \hat{F}, \hat{\delta})$  as follows.

- $\hat{Q} = \mathcal{P}(Q)$ .
- $\hat{q}_0 = \{q_0\}$ .
- $\hat{F} = \{\hat{q} \in \hat{Q} : q \in \hat{q} \text{ for some } q \in F\}$ .
- $\hat{\delta} : \hat{Q} \times \Sigma \rightarrow \hat{Q}$  is the transition function such that

$$\hat{\delta}(\hat{q}, a) = \{q \in Q : (p, a, q) \in \delta \text{ for some } p \in \hat{q}\}.$$

holds for each  $\hat{q} \in \hat{Q}$  and  $a \in \Sigma$ .

Now we prove that  $L(\mathcal{A}) = L(\hat{\mathcal{A}})$ . For  $w \in \Sigma^*$ , let  $\hat{r} = (\hat{r}_0, \hat{r}_1, \dots, \hat{r}_n)$  be the run of  $\hat{\mathcal{A}}$  on  $w$ .

- Suppose that  $r = (r_0, r_1, \dots, r_n)$  is an accepting run of  $\mathcal{A}$  on  $w$ , and we prove that  $\hat{r}$  is an accepting run on  $w$ . It is obvious that  $r_0 \in \hat{r}_0$ . If  $r_{i-1} \in \hat{r}_{i-1}$  for some  $i \in \{1, \dots, n\}$ , then we have  $r_i \in \hat{\delta}(\hat{r}_{i-1}, a_i) = \hat{r}_i$  since  $(r_{i-1}, a_i, r_i) \in \delta$ . Thus,  $r_n \in \hat{r}_n$ , and it follows that  $\hat{r}_n \in \hat{F}$ . Therefore, we have  $L(\mathcal{A}) \subseteq L(\hat{\mathcal{A}})$ .
- Suppose that  $\hat{r}$  is an accepting run. Then due to the construction of  $\hat{F}$  and  $\hat{\delta}$ , we can construct an accepting run  $r = (r_0, r_1, \dots, r_n)$  of  $\mathcal{A}$  on  $w$  as follows.

- Let  $r_n$  be a state in  $\hat{r}_n \cap F$ .
- For  $i \in \{0, \dots, n-1\}$ , let  $r_i$  be a state in  $\hat{r}_i$  such that  $(r_i, a_{i+1}, r_{i+1}) \in \delta$ .

Thus, we have  $L(\hat{\mathcal{A}}) \subseteq L(\mathcal{A})$ , which completes the proof.  $\square$
